Rise, Tarnished is a fantasy action RPG that is about class-based character development that combines three different elements together. Get ready for a ferocious battle against ancient demons. Class-based Character Development Develop your own character following the class system, which has different characteristics between the three types of classes (Warrior, Mage, and Rogue). Strategy Game Lacks the Feel of RPG Gameplay This is the kind of game where you have a turn-based strategic battle that lacks the RPG genre gameplay, such as viewing an enemy's turn-based movements and being able to set your game strategy. The battle system is a classless system that lets you develop your character by yourself, and the characters level-up and gain experience in combat, thus becoming a powerful character. Use a Variety of Weapons and Armor to Defeat an Enemy Equip weapons and armor as you find them, and use them to defeat your enemies. You can also change the appearance of your weapons and armor freely. Funicule, Chocobo, and Guardian Funicule are pets that increase your EXP. The chocobo raises you when you see the message and can be traded. Saga Class and Multistory Dungeon—Authentic Fantasy The Saga class is a new class added in Rise, Tarnished. The class lets you keep some of the skills of the Warrior or Rogue class, but will increase the speed of the levelling up of other classes. The multistory dungeon lets you explore a maximum of 10 floors of a dungeon. Orchestra in Rise, Tarnished also boosts the features of the game. ■ Key Features of Rise, Tarnished -

Bacterial lipopolysaccharides (LPS) are glycolipid molecules found on the outer leaflet of the outer membrane of Gram-negative bacteria. Gram-negative bacteria are generally insensitive to LPS due to the presence of a hydrophobic anchor in the middle of the LPS molecule, and thus the receptor for LPS is always a hydrophilic molecule. C-type LPS, one of the two families of LPS, is a complex carbohydrate bound via the terminal non-reducing end of the lipid A chain, with a decasaccharide core. C-type LPS has been demonstrated to interact with a large family of specific mammalian receptors, including the neonatal Fc receptor (FcRn) and Toll-like receptors (TLRs). Here we describe the purification of a receptor for C-type LPS from the spleen of a chicken, and the generation of antibodies against this receptor. This receptor has similar biochemical characteristics to the mammalian FcRn receptor. Furthermore, we have evidence indicating that this receptor is a TLR. Targeting histamine receptors in the brain controls anxiety in mice. This study examines the long-lasting brain histamine effects on anxiety behavior. It was conducted in mice to evaluate the anxiety-lowering effect of the histamine H1 receptor antagonist, triprolidine and the histamine H2 receptor antagonist, ranitidine. The neurosteroids 17beta estradiol and progesterone, apart from their undoubted action on the classical reproduction endocrine pathways, are also involved in the homeostasis of the brain central nervous system, responding either increasing or decreasing anxiety. Male mice with minimal anxiety, naive or not treated with the drugs, were used. This study shows that, at the dosage of 0.5 mg/kg, the H1 receptor antagonist, triprolidine administered orally and the H2 receptor antagonist, ranitidine administered subcutaneously, reduce the number of vocalizations, the total time and the number of entries onto the center of the open field arena in female but not male mice, reflected by a reduction of the number of bouts, vocalizations and the vertical placing in female mice. The blockade of the histamine receptors did not affect escape attempts, although the number of entries in female mice was reduced. The H1 receptor antagonist triprolidine injected intracerebroventricularly into male and female mice significantly reduces the number of vocalizations and the total time spent in the open field center ($p < 0.01$). The injection of the H2 receptor antagonist, ranitidine did not modify anxiety behavior. When each drug was used in combination, by double administration, with the H1 receptor antagonist and with the H2 receptor antagonist, a different behavioral response was obtained when compared to the single drug effects. The combination of the two H1 and H2 receptor antagonists was not able to produce the anxiolytic effect produced by triprolidine. The triple combination produced an effect in female mice which could only be attributed to the H1 action since not the H2 receptor was involved. The estrous cycle did not influence the effects on
